

WEEK 1 (Day 1)

Python Basics

1. Print Statement – Print messages using print()

```
print("Hope you have a Great Day Ahead :) ")
```

```
C:\Users\bhav\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe C:\Users\bhav\OneDrive\Desktop\DataAn1\first.py
Hope you have a Great Day Ahead :)

Process finished with exit code 0
```

1(a). Printing Multiple lines using Triple Quotations –

```
print("""A very good morning to all
I hope You all are doing well
And it is a pleasure to see you all gathered here :)""")
```

```
C:\Users\bhav\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe C:\Users\bhav\OneDrive\Desktop\DataAn1\first.py
A very good morning to all
I hope You all are doing well
And it is a pleasure to see you all gathered here :)

Process finished with exit code 0
```

2(b). Using (\n) backslash – To insert something in the next line.

```
print("Hello World \nThis is my first Python Program \nAnd I'm implementing next line code")
```

```
C:\Users\bhav\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe C:\Users\bhav\OneDrive\Desktop\DataAn1\first.py
Hello World
This is my first Python Program
And I'm implementing next line code

Process finished with exit code 0
```

2. Variables

Variables are placeholders , which can store a value. In simple words , Variables is a container that holds data inside it as a value.

->Rules for Defining a Variable in Python –

1. Variable name must start with a letter or underscore (_)
2. Variable name cannot start with a number
3. Variable names can contain letters, numbers, and underscores
4. Spaces are not allowed in variable names
5. Variable names are case-sensitive
6. Python keywords cannot be used as variable names

```
Even_num = 1024  
print(Even_num)  
|
```

```
C:\Users\bhavn\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe  
1024  
  
Process finished with exit code 0
```

2. Datatypes –

Data types define the type of value that a variable can store. Python automatically identifies the data type based on the assigned value.

1. Integer (int)

Stores whole numbers (positive or negative).

```
age = 22  
marks = 95  
print("age is -",age)  
print("marks are -",marks)
```

```
C:\Users\bhav\n\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe
age is - 22
marks are - 95

Process finished with exit code 0
```

2. Float (float)

Stores decimal (floating-point) numbers.

```
length = float(input("enter the length of the field(in meters) -"))
print(length)
```

```
C:\Users\bhav\n\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe
enter the length of the field(in meters) - 35.38
35.38

Process finished with exit code 0
|
```

3. String (str)

Stores text or characters inside quotes.

```
name = input("enter your name -")
print(name)
```

```
C:\Users\bhav\n\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe
enter your name - Isabella
Isabella

Process finished with exit code 0
```

4. Boolean (bool)

Stores only two values: True or False.

```
is_pass = True
is_fail = False
print(is_pass)
print(is_fail)
```

```
C:\Users\bhavn\OneDrive\Desktop\DataAn1\.venv\Scripts\python.exe
True
False
```

```
Process finished with exit code 0
```
